

CSE33 I: Microprocessor Interfacing and Embedded Systems

Lecture#11: Interrupt Part#1 (Chapter#11)

Summer, 2023

Mohammad A. Qayum, Ph.D.
ECET, MSNU, Mankato

Interrupts

□ Motivations

- Inform a program of some external events timely
 - Polling vs Interrupt
- Implement multi-tasking with priority support

Merriam-Webster:

“to break the uniformity or continuity of”

Polling vs Interrupt

www.Vecto.rs · 22705

Polling:

You **pick up the phone every three seconds** to check whether you are getting a call.

Interrupt:

Do whatever you should do and pick up the phone **when it rings**.

Interrupt Service Routine Vector Table

- Start address for the exception handler for each exception type is fixed and pre-defined
- Processor loads PC with this fixed, pre-defined address
- Exception Vector Table starts at memory address 0
- Program Counter **pc** = **0x00000004** initially

Address	Priority	Type of priority	Acronym	Description
0x0000_0000	-	-	-	Stack Pointer
0x0000_0004	-3	fixed	Reset	Reset Vector
0x0000_0008	-2	fixed	NMI_Handler	Non maskable interrupt. The RCC Clock Security System (CSS) is linked to the NMI vector.
0x0000_000C	-1	fixed	HardFault_Handler	All class of fault
0x0000_0010	0	settable	MemManage_Handler	Memory management
0x0000_0014	1	settable	BusFault_Handler	Pre-fetch fault, memory access fault
0x0000_0018	2	settable	UsageFault_Handler	Undefined instruction or illegal state
0x0000_001C-0x0000_002B	-	-	-	Reserved
0x0000_002C	3	settable	SVC_Handler	System service call via SWI instruction
0x0000_0030	4	settable	DebugMon_Handler	Debug Monitor
0x0000_0034	-	-	-	Reserved
0x0000_0038	5	settable	PendSV_Handler	Pendable request for system service
0x0000_003C	6	settable	SysTick_Handler	System tick timer
...				

ISR Vector Table

For interrupt number n:
CMSIS Interrupt Number = 16 + n

Stacking & Unstacking

- **Stacking:** The processor automatically pushes these eight registers into the main stack before an interrupt handler starts
- **Unstacking:** The processor automatically pops these eight registers out of the main stack when an interrupt handler exits.

- Two stack pointers: Main SP (MSP) and Process SP (PSP)
- Determined by operating mode, and bit 0 of the CONTROL register
 - Handler mode $\rightarrow$ SP = MSP
 - Thread mode $\rightarrow$ SP = MSP, if CONTROL[0] = 0 (i.e., privileged thread mode);
SP = PSP, if CONTROL[0] = 1 (i.e., unprivileged thread mode)

Interrupt

Stacking & Unstacking

Registers

MSP: Main Stack Pointer

PSP: Process Stack Pointer

Processor Mode: Handler Mode *vs* Thread Mode

- Handler mode and Thread mode
 - Handler mode always use **MSP** (Main Stack Pointer)
 - Thread Mode uses either **PSP** (Process Stack Pointer) or **MSP**
 - $\text{Control}[1] = 0$, $\text{SP} = \text{MSP}$ (default)
 - $\text{Control}[1] = 1$, $\text{SP} = \text{PSP}$
- When the processor is reset, the default is the thread mode.
- The processor enters the handler mode when an exception occurs.

Register values in a interrupt service routine

LR = 0xFFFFFFFF9

SP = MSP

ISR always in
handler mode.

The screenshot shows a debugger interface with the following components:

- Registers Window:** Displays the state of various registers. The 'Core' registers R0-R12 are shown with their values. R13 (SP) is 0x200005C8, R14 (LR) is 0xFFFFFFFF9, and R15 (PC) is 0x0800017C. The 'Banked' registers show MSP at 0x200005C8. The 'System' registers show BASEPRI, PRIMASK, FAULTMASK, and CONTROL all at 0x00. The 'Internal' window shows the processor is in 'Handler' mode.
- Disassembly Window:** Shows the assembly code for the 'SVC_Handler' procedure. The current instruction at address 0x0800017C is 'CPSID I', which disables interrupts. Other instructions include 'EXPORT SVC_Handler', 'POP {r4-r5, pc}', 'PUSH {r4-r8, lr}', 'LDR r7, [sp, #0x14]', 'TST r7, #0x04', 'ITE EQ', 'MRSEQ r4, msp', 'MRSNE r4, psp', 'LDR r4 = 0x080001A3', 'LDR r6, [r4, #0x04]', 'MOV r0, r6', 'BLX r5', and 'BX lr'.
- Code Windows:** The bottom of the interface shows two code windows: 'stm32l1xx_constants.s' and 'startup_stm32l1xx_md.s'.

Which stack to use when exiting an interrupt?

Link Register (LR) now has two usages:

- LR = address of the instruction immediately after BL
- LR indicates whether MSP or PSP is used to restore register from when exiting an interrupt
 - LR value generated by processor
 - The processor set LR to **0xFFFFFFFF** on reset.
 - If return to handler mode, the MSP stack is always used

Which stack to use when exiting an interrupt?

Link Register (LR) now has two usages:

- LR = address of the instruction immediately after BL
- LR indicates whether MSP or PSP is used to restore register from when exiting an interrupt

No FP extension:

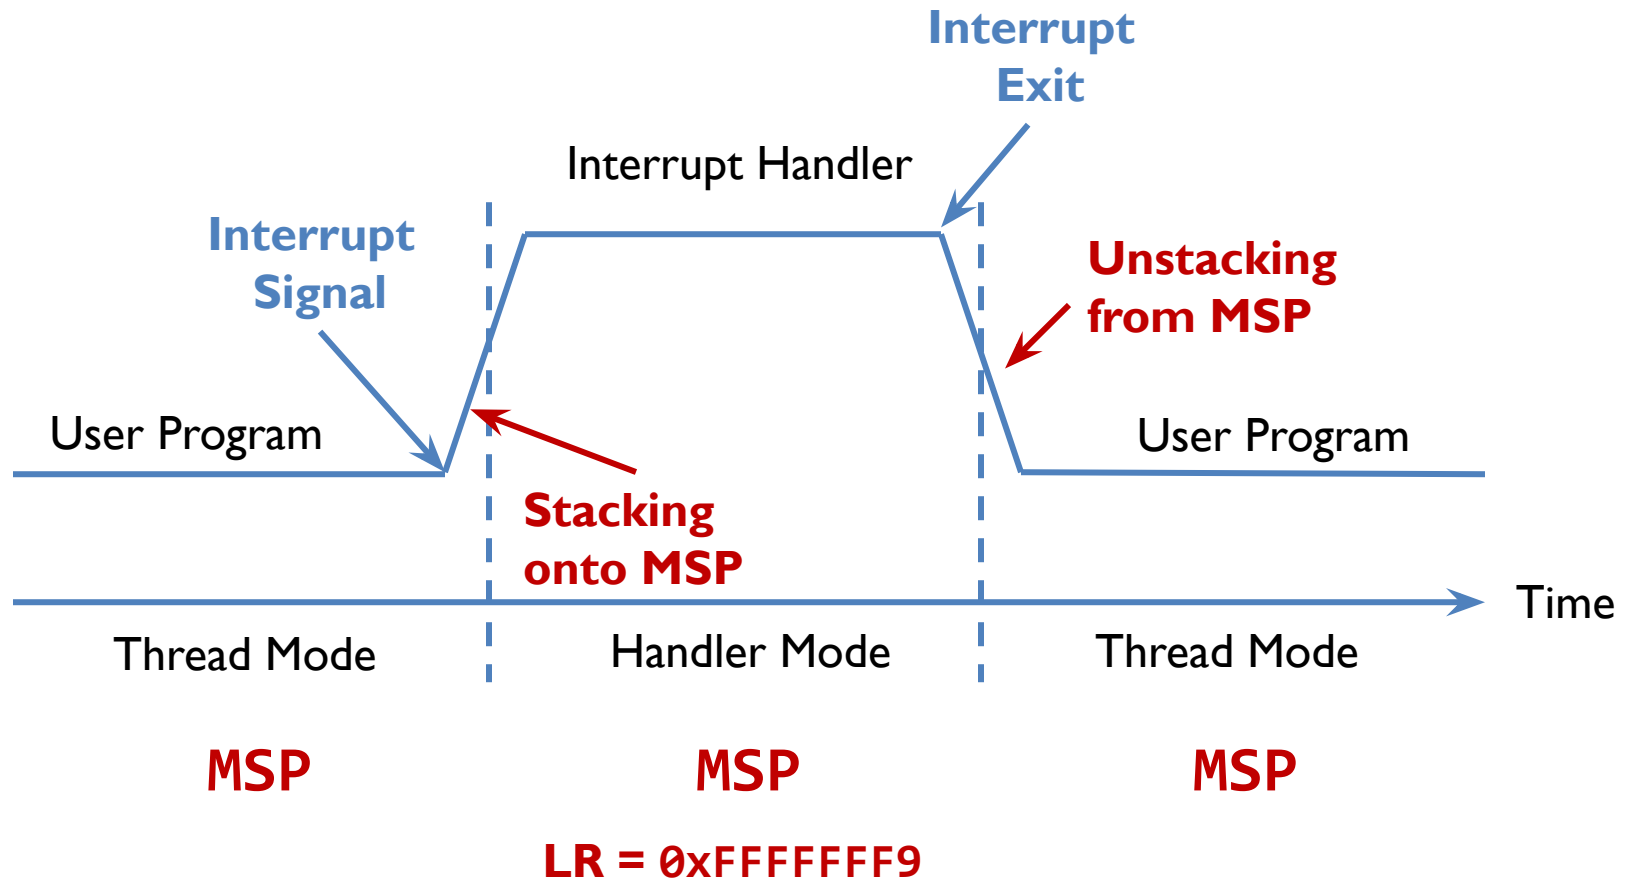

Link Register (LR)	Return Mode	Return Stack
0xFFFFFFFF1	Handler	SP = MSP
0xFFFFFFFF9	Thread	SP = MSP
0xFFFFFFFDD	Thread	SP = PSP

With FP extension:

Link Register (LR)	Return Mode	Return Stack
0xFFFFFFE1	Handler	SP = MSP
0xFFFFFFE9	Thread	SP = MSP
0xFFFFFDED	Thread	SP = PSP

Stacking & Unstacking

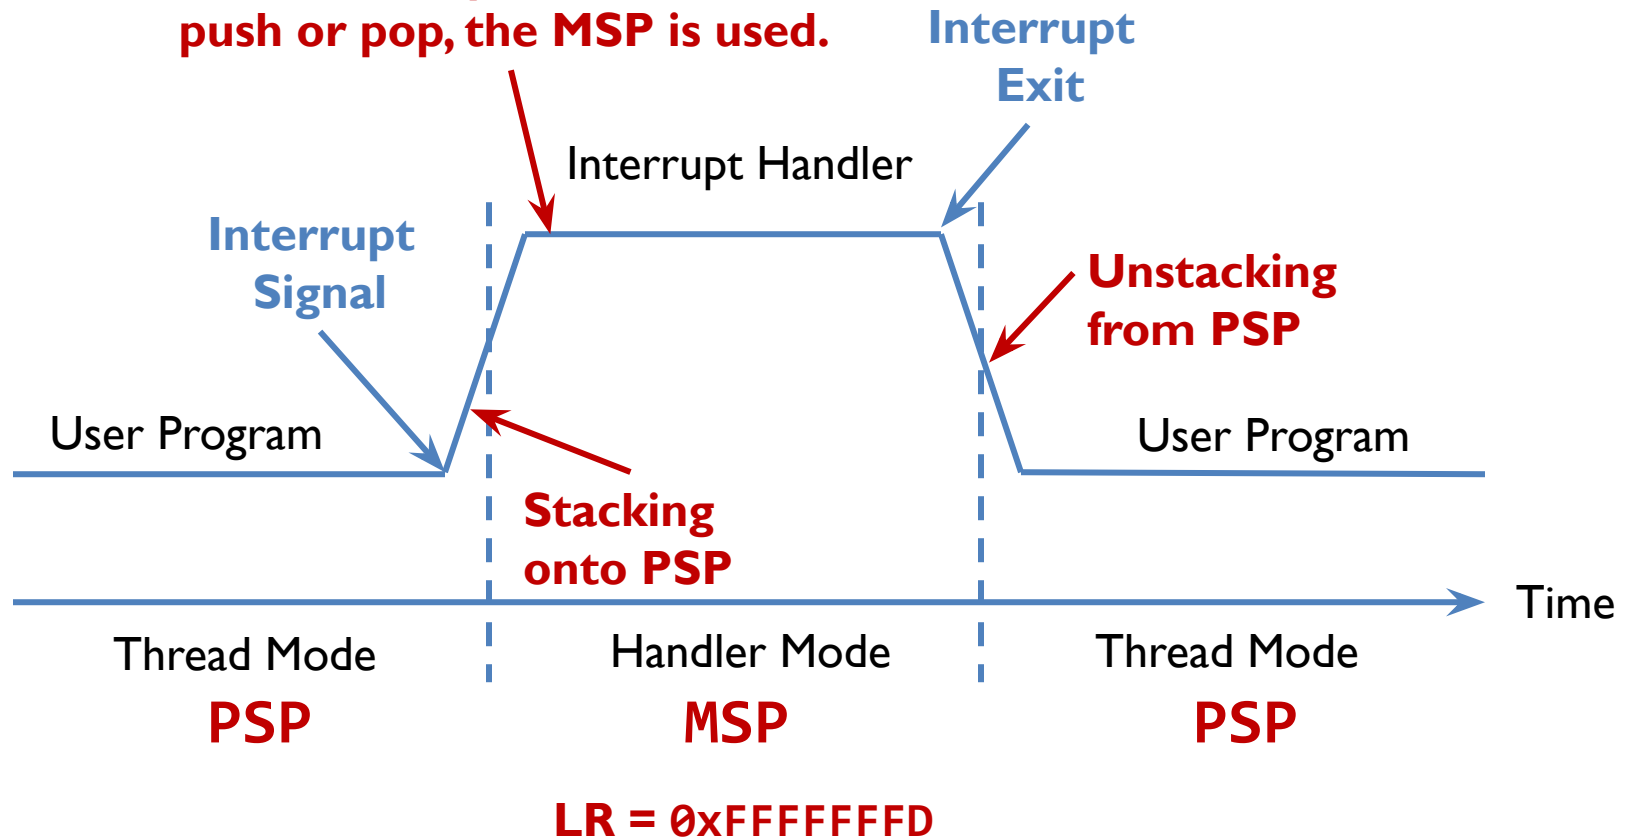

Control[1] = 0 $\Rightarrow$ User program uses MSP.

Stacking & Unstacking

Control[1] = 1 $\Rightarrow$ User program uses PSP.

**If the interrupt handler calls
push or pop, the MSP is used.**

Which is being used?

When exiting an interrupt:

- If **LR = 0xFFFFFFFF9**, then **SP = MSP**
- If **LR = 0xFFFFFDD**, then **SP = PSP**

9 = 1001

D = 1101

```
TST    r7, #0x04
MRSEQ  r4, msp
MRSNE  r4, psp
STMFD  r4!, {r7-r9} ; Push onto a Full Descending Stack
```

Interrupt: Stacking & Unstacking

```
__main PROC
...
MOV r3, #0
...
ENDP

SysTick_Handler PROC
EXPORT SysTick_Handler
ADD r3, #1
ADD r4, #1
BX lr
ENDP
```
